## Luftgütedaten 2017 Nationaler und europäischer Städtevergleich

### Einführung

Die Bekämpfung der Luftverschmutzung ist nach wie vor eines der zentralen Themen, mit denen Umweltämter, Umweltbehörden bzw. sonstige für den Umweltschutz tätige Organisationen beschäftigt sind. In Form von regionalen oder nationalen Luftreinhalteplänen wird versucht, die Luftverschmutzung in den Griff zu bekommen und die Luftqualität sukzessive zu verbessern. In den letzten Jahren ist die Belastung an Feinstaub (PM<sub>10</sub> und PM<sub>2,5</sub>) und Stickoxiden besonders in den Mittelpunkt des Interesses gerückt, da die Grenzwerte für diese Luftschadstoffe in den meisten Ballungsräumen überschritten werden.

Um überhaupt den Erfolg von Sanierungsmaßnahmen nachweisen zu können, ist die Beobachtung der Schadstoffkonzentrationen mit Hilfe von Luftmessnetzen sinnvoll. In den meisten Messgebieten sind Luftmessnetze seit mehr als 3 Jahrzehnten installiert, sodass bei einer Verfolgung der Luftschadstoffdaten über mehrere Jahre ein Trend zur Verbesserung (oder auch Verschlechterung) der Luftbelastung herauslesbar ist. Sanierungsmaßnahmen in Betrieben und bei anderen Emittentengruppen müssen sich langfristig in einer verminderten Immissionsbelastung an Luftschadstoffen manifestieren.

Die Verfolgung *längerer Zeiträume* zur Bestimmung des Belastungstrends ist unbedingt notwendig, da auf Grund von unterschiedlichen meteorologischen Einflüssen die Immissionsbelastungen außerordentlich stark schwanken können. Beispielsweise wird ein Monat mit vornehmlich regnerischer Witterung und viel Wind wesentlich geringere Immissionskonzentrationen aufweisen als ein Monat, in dem häufig Inversionswetterlagen vorherrschen.

## Air Quality Data in 2017 The Comparison of Cities and Regions in Europe

### Introduction

The fight against air pollution is still one of the major topics organisations concerned with environmental affairs, such as national and local authorities are dealing with. Attempts are made to get air pollution under control and increase the air quality step by step establishing regional or national air-cleaning programmes. During the last years the pollutant stress of fine particulates (PM<sub>10</sub> and PM<sub>2,5</sub>) and nitrogen oxides has become more important, since the European air quality standards of these pollutants are exceeded in most of the agglomerations.

To prove the success of measurements of redevelopment at all, the observation of the concentrations concerning air pollutants by means of monitoring station networks is useful. In most of the referred monitored areas air quality monitoring station networks have been installed for more than 3 decades. By following the air quality data through a longer period of years a trend for improvement (or even a change to the worse) of the air-pollutant stress can be recognized. Measurements of redevelopment in companies, factories and other groups of emission sources should be visible as a reduced immission stress of air pollutants.

It is absolutely necessary to determine the trends of pollution throughout a *longer period of time*, because various meteorological influences can cause an extreme alteration of the immission stress. For instance, a month with mostly rainy weather conditions and high wind speeds will lead to a much lower immission stress in comparison with a month, when the formation of inversion layers can be observed frequently.

Luftgütevergleiche werden durch die Stadt Linz bereits seit vielen Jahren durchgeführt, genau genommen seit 1989. Anfänglich wurden nur österreichische Städte miteinander verglichen. In den folgenden Jahren wurde der Städtevergleich aufgrund des großen Interesses auf immer mehr europäische Städte und Regionen ausgedehnt. Im Jahr 2017 wurden Städte bzw. Regionen aus Österreich, Deutschland, Großbritannien, Frankreich, Schweden, Italien, Schweiz, Spanien, Polen, Dänemark, Tschechien, Ungarn, Lettland, Portugal, Rotterdam und Kroatien mit einbezogen. Die Städte Bratislava, Luxemburg, Belgien und Sofia lieferten für das Jahr 2017 keine Daten.

Die Stadt Bukarest liefert seit 16 Jahren keine Daten mehr. Sollten diese noch eintreffen, werden sie in künftigen Städtevergleichen in Form von Zeitreihen mit berücksichtigt.

Seit dem Jahr 2008 wurde der Luftgütevergleich mit dem lungengängigen Feinstaubanteil  $PM_{2,5}$  ergänzt, da diese Partikel erhebliche negative Auswirkungen auf die menschliche Gesundheit besitzen.

Die Größe des Immissionsgebietes und die Bevölkerungszahl wurden ebenfalls seit 2008 in den Luftgütevergleich aufgenommen, um die Messstellendichte miteinander zu vergleichen.

Comparisons of the air quality have been carried out by the City of Linz already for a number of years, exactly since 1989. At first only Austrian Cities were compared. The comparison was extended to other European cities and regions during the last year as a result of growing interest in such studies. The comparison of the air quality of the year in 2017 comprised cities and regions of Austria, Germany, cities from Great Britain, France, Sweden, Italy, Switzerland, Spain, Poland, Denmark, Czech Republic, Hungary, Latvia, Portugal, Rotterdam, Slovakia and Croatia. We did not receive data from the city of Bratislava, Luxemburg, Belgium and Sofia in 2017.

The city of Bucharest has not been delivering any data for 16 years. In case a delivery will follow, it will be taken into account for future reports in terms of time series.

Since 2008 the comparison of the air quality has been extended with fine particulate matter  $PM_{2,5}$ . These respirable particles are responsible for significant negative impacts on human health.

Since 2008 the comparison has been extended by the immission area and the population in order to compare the closeness of the measurement points.

## Kritische Anmerkungen

Als Kritikpunkt wird immer wieder angemerkt, dass ein Vergleich der Immissionsbelastung aus fachlichen Gründen nicht möglich sei, da

1. die Zahl der Messstellen sehr verschieden ist (die Anzahl der Messstellen pro Messgebiet ist in der Tabelle auf Seite 16 und den nachfolgenden Grafiken angeführt),
2. die Messstellendichte unterschiedlich ist,
3. die Situierung der Messstellen nicht immer vergleichbar ist (In manchen Städten wurde deswegen bei den Schadstoffkomponenten zwischen verkehrsbelasteten Messstationen und anderen Messstationen unterschieden).

Die Autoren sind sich dieser Tatsachen durchaus bewusst. Trotz der erhobenen Einwände gibt es einige Argumente für die Fortführung der Städtevergleiche:

1. Die Luftschadstoffmessungen werden im Allgemeinen technisch in der gleichen oder in ähnlicher Weise durchgeführt. Das bedeutet, dass die Luftüberwachung an bestimmten *Punkten* einer Stadt oder einer Region mit Hilfe automatisch registrierender Immissionsmessstationen durchgeführt wird. Die gemessenen Konzentrationen repräsentieren die Belastung eines mehr oder weniger weiten Bereiches um die Messstation. Die *Art der Probenahme* müsste also *vergleichbar* sein.
2. Die Luftgütestationen sollten an Punkten errichtet werden, die einen größeren Bereich um die Messstation abdecken und nicht nur die Schadstoffbelastung an einem bestimmten Punkt widerspiegeln. Ausgenommen sind besondere verkehrsbelastete Probenahmepunkte. Die Messnetzbetreiber wurden eingeladen, diese Messpunkte getrennt anzugeben, um die wirkliche Situation des überwachten Gebietes wiederzugeben. Wie bereits erwähnt, unterscheiden einige Städte zwischen verkehrsbelasteten und nicht vom Verkehr beeinflussten Messstationen.

## Critical remarks

Over and over again it is critically remarked that it is not possible to compare the pollutant stress between monitoring areas. The following technical reasons are mentioned by some monitoring network services:

1. The number of monitoring stations is very different (see table on page 16 and the subsequent charts),
2. the density of distribution of the monitoring stations is different,
3. the location of the monitoring stations is not always comparable (for that reason in some cities the network services distinguish between traffic-stressed and non-traffic-influenced monitoring stations).

The authors of this comparative study are thoroughly conscious of these facts, but despite the raised objections there are also some arguments of the activities:

1. The way of measurement of air pollutants is carried out by the same or similar technical methods. This means, the results of air monitoring activities are obtained by sampling at special sampling *points* in a city or region by means of automatically recording monitoring stations. The registered concentrations represent the stress of a more or less wide area around the monitoring station. Due to this reason the *method of sampling* itself should be *comparable*.
2. The monitoring stations should be located at points representing a wider portion of the monitored area, not only the pollution stress representative for a focal point. Exceptions are designated traffic stressed sampling points. The runners of monitoring station network services were invited to separate such monitoring points in order to represent the real situation of the monitored area. As already mentioned, some cities distinguish between traffic-stressed and non-traffic-influenced monitoring stations.

3. Schließlich wird eine stärker objektivierende Basis der Auswertungen besonders dann erreicht, wenn längere Zeiträume betrachtet werden und daraus die Trendentwicklung der Schadstoffimmissionen abliest. Nachdem die Stadt Linz internationale und nationale Städtevergleiche schon seit vielen Jahren durchführt, gibt es für die Jahresmittelwerte auch die mehrjährige *Trendentwicklung* der Schadstoffbelastung seit 1993 für die Immissionsgebiete. Die Daten von Städten bzw. Regionen, die erst seit kurzem im Städtevergleich integriert sind, wurden dabei auch so weit wie möglich nachgeführt.

3. In the end the evaluations are put to a more objectified basis, when long term developments are observed and thereof the trends of the pollutant immission can be derived. Since the city of Linz has been carrying out comparisons of the air quality for many years, this report also contains the *trend developments* for the annual mean values since 1993 for the immission regions. The data of cities or regions which only have been participating the comparison for a couple of years have been updated as far back as possible.

## Immissionskenngrößen

In der vorliegenden Studie wurden verschiedene Immissionskenngrößen erhoben:

- Jahresmittelwert (Mittel aus allen Stationen einer Stadt/Region)
- Max. Monatsmittelwerte (höchstbelastete Station einer Stadt/Region)
- Max. Tagesmittelwert (höchstbelastete Station einer Stadt/Region)
- Max. Einstunden-Mittelwert (höchstbelastete Station einer Stadt/Region)
- Max. 98-Perzentil/Jahr (höchstbelastete Station einer Stadt/Region)
- Anzahl der Überschreitungen des PM<sub>10</sub>-Tagesgrenzwertes an der höchstbelasteten Messstation
- Anzahl der Überschreitungen des NO<sub>2</sub>-Grenzwertes für den 1h-Mittelwert an der höchstbelasteten Messstation

Von den einzelnen Messnetzbetreibern wurden die gewünschten Immissionsdaten in sehr unterschiedlicher Vollständigkeit zur Verfügung gestellt. Insbesondere betrifft dies die Perzentil-Auswertungen. Oftmals ist auch nicht das 98-Perzentil verfügbar, sondern es werden andere Perzentilgrößen (z. B. 95-Perzentil) gebildet. Die meisten Messnetzbetreiber berechnen die Perzentile aus den Halbstunden-Mittelwerten eines Jahres, manchmal werden jedoch auch die Tagesmittelwerte dafür herangezogen.

Wie schon in den letzten Berichten ist der vorliegende Bericht bei den grafischen Auswertungen kürzer gefasst als vor dem Jahr 2006. Seit damals wurden die grafischen Darstellungen für die Perzentile, die max. 3-Stunden-Mittelwerte, die max. Halbstundenmittelwerte und die max. Monatsmittelwerte, da sie im Allgemeinen von weniger starkem öffentlichem Interesse sind, herausgenommen. Aufgenommen wurden hingegen die grafischen Auswertungen über 1-Stunden-Mittelwerte, die nunmehr fast überall die Norm für die Bewertung von Kurzzeitbelastungen darstellen.

Es wurde also nur ein Teil der zur Verfügung gestellten Luftgütekennzahlen für die Grafiken verwendet. Die kompletten Datensätze können aus den Übersichtstabellen im Anhang entnommen werden.

## Immission reference values

The present study various immission reference values have been surveyed, such as:

- annual mean value (mean of all monitoring stations of a city/region)
- Max. monthly mean value (max. stressed monitoring station of a city/region)
- Max. daily mean value (max. stressed monitoring station of a city/region)
- Max. 1-hours mean value (max. stressed monitoring station of a city/region)
- Max. 98-Percentile/year (max. stressed monitoring station of a city/region)
- Number of violations of the PM<sub>10</sub> daily mean standard at the highest stressed monitoring station
- Number of violations of the NO<sub>2</sub> 1h mean standard at the highest stressed monitoring station

The runners of air pollution monitoring networks support us with immission data of very different completeness, especially referring to the evaluation of the percentiles. Often the 98-Percentile is not available but the value for the 95-Percentile is given. In most of the monitoring networks the percentiles are calculated based on the *1/2-hours mean* values of a calendar year, sometimes they were based on the *daily mean* values.

Regarding the graphical evaluations of immission reference data the present report has been shortened as already done in the latest reports. Since 2006 the graphical presentation of percentiles, max. 3h mean values, max. monthly mean values, 1/2h mean values have not been carried out any more, as a result of minor public interest. On the other hand the max. 1h mean values are graphically presented now, since they are a widely-used evaluation standard for short term stress.

Only a part of the provided air quality values has been used for graphical evaluation. The whole data set can be obtained from the overview tables of the annex.

## **Verglichene Luftschadstoffe**

Folgende Luftschadstoffe wurden miteinander verglichen:

SO<sub>2</sub>, CO, NO, NO<sub>2</sub>, O<sub>3</sub>, Feinstaub (PM<sub>10</sub> und PM<sub>2,5</sub>)

Anmerkung:

Schwebstaub (TSP) wurde nicht mehr ausgewertet, da die Messungen in den einzelnen Messgebieten mittlerweile durch PM<sub>10</sub>-Messungen ersetzt worden sind.

## **Mehrjahresvergleich**

Ein gutes Bild über die Entwicklung der Luftbelastung geben die Grafiken wieder. Dabei wurde von den am Luftgütevergleich teilnehmenden Städten die Entwicklung der Immissionsbelastung von 1993 bis 2017 aufgetragen.

Nach Analyse der Daten können folgende Aussagen getroffen werden:

1. Einige Städte und Regionen haben ein dichtes Messstellennetz bezogen auf die Größe des Immissionsgebietes. Beispiele: Athen, Berlin, Linz, Wien. Andererseits werden manchmal sehr große Gebiete durch eine geringe Zahl von Messstationen überwacht.
2. Aufgrund dieser Tatsache ist die Vergleichbarkeit einzelner Regionen begrenzt.
3. Die Belastungen (Jahresmittelwerte) einzelner Regionen und Städte haben sich einander sehr angenähert. Einige Städte/Regionen ragen allerdings noch deutlich heraus.
4. Bei einigen Städten kann man erkennen, dass in jenen Situationen, bei denen 1993 relativ hohe Immissionsbelastungen registriert wurden, seitdem oftmals eine deutlich sichtbare Besserung der Immissionssituation eingetreten ist, während in Städten mit niedriger Immissionsbelastung im Vergleich dazu kaum eine Änderung der Luftbelastung eingetreten ist.
5. Es zeigt sich, dass in den Städten und Regionen die Schwebstaub-(TSP)-Messungen abgeschaltet wurden. Diese Messungen wurden von Feinstaub (PM<sub>10</sub>-Messungen und zunehmend PM<sub>2,5</sub>) abgelöst. TSP-Messungen werden daher seit einigen Jahren nicht mehr in die Auswertungen miteinbezogen.

## **Pollutants compared**

The following air pollutants have been compared:

SO<sub>2</sub>, CO, NO, NO<sub>2</sub>, O<sub>3</sub>, fine particulates (PM<sub>10</sub> and PM<sub>2,5</sub>)

Remark:

TSP has not been evaluated any more due to the fact that in most monitoring networks the TSP measurements are already replaced by monitoring of PM<sub>10</sub>.

## **Comparison over a period of years**

A good impression of the development of air pollutant stress can be received by the graphical evaluations. Therefore the immission stress for the area of each participating city and region from 1993 through 2017 are plotted.

The following statements can be given when analysing the data:

1. Some cities and regions have - according to the area - a high monitoring network density. Examples: Athens, Berlin, Linz, Vienna. On the other hand very large areas are monitored only by a small number of stations.
2. Due to this fact the comparability between regions is limited.
3. The range of the annual mean immission stress between the cities/regions has become lower and lower since 1993. But some cities/regions are still remarkably higher stressed than the rest.
4. In some cities it can be seen that in regions where pollution stress was relatively high in 1993, a significant decrease could be observed, while in cities with low immission stress compared to other cities and regions there was hardly any change of air pollution.
5. It can be shown that cities and regions do not monitor TSP anymore. These measurements were replaced by monitoring the pollutant PM<sub>10</sub> and more and more PM<sub>2,5</sub>. This is the reason TSP measurements have not been included anymore for a couple of years in the present report.

6. Entwicklung der Langzeitbelastung - Jahresmittelwerte SO<sub>2</sub>, Schwebstaub (TSP) (nur bis 2004!), NO, NO<sub>2</sub>, CO, und O<sub>3</sub> gegenüber 1993; PM<sub>10</sub>: gegenüber 2001; PM<sub>2,5</sub>: gegenüber 2008:

SO<sub>2</sub>: Alle Regionen *geringer* belastet

Staub: TSP-Messung in nahezu allen Regionen eingestellt. Wenn vorhanden, ist die Tendenz zu *geringeren* Belastungen (Vergleich nur bis 2004).

PM<sub>10</sub>: tendenziell *geringer belastet*

PM<sub>2,5</sub>: uneinheitlich, tendenziell gleich bleibend oder *geringer belastet*

NO: uneinheitlich, tendenziell gleich bleibend oder *geringer belastet*

NO<sub>2</sub>: uneinheitlich, tendenziell *geringer belastet* oder gleich bleibend

CO: alle Regionen *geringer* belastet

O<sub>3</sub>: Belastung tendenziell *gleich bleibend* oder *leicht erhöht*

6. Long term development of the air pollution stress - annual mean values of SO<sub>2</sub>, TSP (only until 2004!), NO, NO<sub>2</sub>, CO, O<sub>3</sub> in comparison with 1993; for PM<sub>10</sub>: comparison with 2001; for PM<sub>2,5</sub>: comparison with 2008:

SO<sub>2</sub>: All regions *less* stressed

TSP: Nearly no TSP-measurements any more. If there is still monitoring, regions are *less* stressed in tendency (Comparison only up to 2004).

PM<sub>10</sub>: trend is *lower* stressed

PM<sub>2,5</sub>: non-uniform, trend constant or *lower* stressed

NO: non-uniform, trend of *lower* stress or constant

NO<sub>2</sub>: non-uniform, trend is *lower* stressed or constant

CO: all regions trend of *lower* stress

O<sub>3</sub>: trend is constant or *slightly higher* stressed

Legend:  Slightly stressed (SO<sub>2</sub> < 15 µg/m<sup>3</sup>)  
 Medium stressed (SO<sub>2</sub> < 30 µg/m<sup>3</sup>)  
 Highly stressed (SO<sub>2</sub> > 30 µg/m<sup>3</sup>)

 no data

<sup>1)</sup> TSP measurements are mostly replaced by PM<sub>10</sub> monitoring (see page 24). So no comparison of TSP has been carried out since 2004. If you are interested in TSP-values until 2005 please refer to the report of 2005 (available via internet, URL <http://www.linz.at/umwelt/4109.asp>)

<sup>2)</sup> ... or year when data were primarily available

- No Data

<sup>9)</sup> Bei den Werten wurden bereits die Korrekturfaktoren berücksichtigt. Diese sind aus den Tabellen im Anhang zu ersehen.

<sup>10)</sup> Nähere Details zur Unterscheidung zwischen verkehrsbelasteten Stationen und sonstigen urbanen Messstationen siehe Tabellen am Ende des Berichtes bzw. diverse grafische Auswertungen.

<sup>11)</sup> For the number of exceedances the correction factors already have been considered. One can refer to the tables at the end of the report.

<sup>12)</sup> For details in order to distinguish between traffic stressed stations and other urban monitoring stations see tables at the end of the report and the graphical evaluations.

## Comments:

The highest value are from the fireworks on the first hour of newyears day! The second High Value is without the piek of the fireworks.

\*\* First number is 98 percentiel of the daily values, second number is 98 percentiel of the hourly values.

\*\*\* We have used two correction factors in 2017, that is because we have changed to a different brand of filtertape in the BAM 1020.

\*\*\*\* All PM numbers are including the correction factors.

\*\*\*\*\* The measurements are done in the Rotterdam Rijnmond Area

We have stopped the monitoring of CO since 2017 and we do not have ½ hourly values in our system.

Bold printed monitoring stations: additionally gravimetric method used

99.9-Percentile values (MW1) of PM<sub>10</sub> and PM<sub>2,5</sub> are from continuous measurements (including station factor). This applies also for stations with continuous and gravimetric measurements, because the gravimetric method delivers only daily mean values.

All other particulates values (annual mean, max. MMW and max. daily mean) are derived preferably from gravimetric monitoring.
